

Scenario Description

This scenario describes the core interactions in the goods management process of the Warehouse Management System, focusing on the order-to-sale workflow:

1. The process begins when the Retailer identifies that stock levels are low.
2. The Retailer sends an order request to the Supplier (Order Goods()).
3. The Supplier processes the order and delivers the requested items back to the Retailer (Goods Supplied()).
4. After receiving the goods, the Retailer initiates the arrangement process by sending a request to organize the goods in the warehouse (Arrange Goods()).
5. The warehouse system processes this request and confirms when the goods have been properly arranged by product category or price (Goods Arranged()).
6. When a Customer arrives, the Retailer initiates a sales transaction by offering goods to the Customer (Sell Goods()).
7. The Customer completes the purchase, and the system records the transaction and updates inventory levels (Goods Sold()).
